1 Overview and Objectives

This lab will introduce MOOS to new users. It assumes nothing regarding MOOS background. The goals of this lab are to (a) understand the publish-subscribe architecture, (b) get comfortable launching and interacting with the MOOSDB, (c) understand how to generate scripted interactions with the MOOSDB, (d) understand how the logger operates and basic tools for examining log files

- MOOS Preliminaries: MOOS vs. MOOS-IvP, the MOOS Architecture
- Launching, Scoping, and Poking the MOOSDB
- Launching a Mission with pAntler
- Scripted Pokes the to the MOOSDB
- A Simple Example with pXRelayTest
- Modify the pXRelayTest Code

1.1 Preliminaries 先確定一下你的環境行不行

This lab assumes you have a working MOOS-IvP tree checked out and built on your computer. To verify this make sure that the following executables are built and findable in your shell path:

```
$ which MOOSDB
/Users/you/moos-ivp/bin/MOOSDB
$ which pHelmIvP
/Users/you/moos-ivp/bin/pHelmIvP
```

If unsuccessful with the above, return to the steps in Lab 1: http://oceanai.mit.edu/ivpman/labs/machine_setup

1.2 MOOS vs. MOOS-IvP

What is the relationship between MOOS and MOOS-IvP? MOOS-IvP is a superset of MOOS. The additional components include another architecture, the IvP Helm behavior-based architecture, and several additional MOOS applications. This is the nested repository concept depicted in Figure 1.

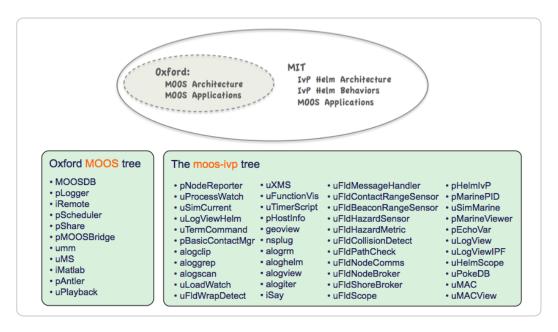

Figure 1: Nested Repositories: The MOOS-IvP tree contains the Oxford MOOS tree and additional modules from MIT including the Helm architecture, Helm behaviors and further MOOS applications.

```
哈佛寫一些最基礎了,MIT在上面
再寫了一些,
蓋了一個IVP
```

1.3 More MOOS / MOOS-IvP Resources

We will only just touch the MOOS basics today. A few further resources are worth mentioning for following up this lab with your own exploration.

- The 2.680 lecture covers much of the material for today's lab: http://oceanai.mit.edu/2.680/lectures/2.680-03-moos-intro.pdf
- The "Very Brief Overview of MOOS" page on the course documentation page: http://oceanai.mit.edu/ivpman/pmwiki/pmwiki.php?n=Helm.MOOSOverview
- Follow the links to the documentation on the Oxford MOOS website. http://themoos.org

1.4 The MOOS Architecture

跟ROS很像嘛

一個核心控很多個應用

The main idea explored today is that MOOS is a publish-subscribe architecture. A single MOOSDB serves multiple MOOS applications by essentially handling the mail published and subscribed for by each app. A MOOS *community* is a collection of applications connected to a single MOOSDB.

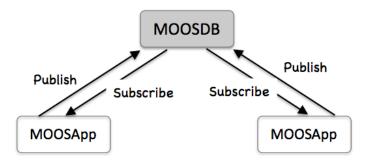

Figure 2: The MOOS Architecture: MOOS is a publish-subscribe architecture. The MOOSDB serves a number of clients, handling mail for each client as new information is posted. A MOOSDB with connected clients constitutes a MOOS community. There may be multiple MOOS communities on a single machine, and a single MOOS community may be distributed over more than one machine.

很多社區在同一台機器上或是一台機器上有很多社區都是有可能的

For typical autonomous vehicle implementations, there is a MOOS community on board each vehicle. When simulating multiple vehicles on a single machine, there is also a single community associated with each vehicle. A MOOS community consists of a single MOOSDB with one or more connected clients. The communications discussed in today's lab concern how a single app communicates with another app via the MOOSDB in the publish-subscribe architecture. Later labs will address how vehicles communicate with each other, essentially bridging two or more MOOS communities with one another.

For today, the focus is on the MOOSDB and connected applications. The MOOSDB, unlike an actual database, does not contain a full history of information that has passed through it. At most, it stores the latest value for any given MOOS variable published to the MOOSDB. When a new app connects to the MOOSDB it must register for the mail it needs. On startup, an app can expect to get a mail message containing the latest value for any variable it registers for, even if that mail reflects a posting to the MOOSDB long ago. Anything happening prior to that will be unknown to the newly connected app.

因為前面有說嘛,不會記錄歷史資料, 所以新connect的不會知道之前發生什麼事

2 Launching the MOOSDB

Here we describe how to launch the MOOSDB from the perspective of the first-time user. The MOOSDB application is a server that runs on the robot or unmanned vehicle computer, or simply on your laptop during simulation. It may be launched from the command line, assuming it is in your path. Two minimalist methods are described here, starting with the most bare-bones.

2.1 A Bare-Bones Launching of the MOOSDB

In a bare-bones manner, the MOOSDB may be launched from the command line without any arguments. Normally the MOOSDB needs to know at least two pieces of configuration information, (a) the machine (IP address) on which to run, and (b) the port number on which to serve clients. It will default to running on the localhost and port 9000:

At this point the MOOSDB is running on the local machine, serving clients on port 9000. A few variables are already being published, by the MOOSDB itself. You can open a scope with uXMS in another terminal window:

The Source and Time columns may be expanded by hitting the "s" and "t" keys respectively after it launches, or you can add --show=source, time as a command line argument to uXMS, to launch with these two columns expanded.

Alternatively you can scope with the umm tool:

```
$ umm --spy
```

2.2 A More Civilized Launching of the MOOSDB

.moos 的檔

Virtually all MOOS applications are launched with a "mission configuration" file, a.k.a. a "dot-moos" file. The below mission file, moosdb_alpha.moos, provides the minimal configuration parameters the MOOSDB likes to see upon starting.

```
// (wget http://oceanai.mit.edu/2.680/examples/moosdb_alpha.moos)
ServerHost = localhost
ServerPort = 9000
Community = alpha
```

Passing the moosdb_alpha.moos file as a command line argument produces the below output.

Try this. Either copy and paste the above .moos file, or use wget as shown on the first line above in the example file. If you haven't installed wget or similar (e.g., curl), you should pause here and do that.

3 Scoping the MOOSDB

A MOOS scope is a tool for examining the state of the MOOSDB. The MOOSDB does not keep a history of prior values for a given variable, but rather just the most recent value posted. This means that the state of the MOOSDB may be regarded as the set of current MOOS variables, their values, and who made the last posting to the variable and when. Scoping allows a view into the current state (or even recent history) of the MOOSDB. There are multiple tools for scoping the DB, each providing conveniences of one kind or another. Here we describe the uXMS and uMS tools, the two favorites of our own lab.

More info on these two tools can be found at:

```
• uXMS: http://oceanai.mit.edu/ivpman/apps/uXMS
```

• uMS: http://www.themoos.org

3.1 Scoping the MOOSDB with uXMS

開uXMS來看MOOSDB裡的var

Your goals in this part are:

1. Open a terminal window and launch the MOOSDB as done at the end of the previous exercise:

```
$ MOOSDB
------ MOOSDB V10 -----
Hosting community "#1"
Name look up is off
Asynchronous support is on
Connect to this server on port 9000
------
network performance data published on localhost:9020
listen with "nc -u -lk 9020"
```

The MOOSDB is normally launched with a mission file specifying the ServerHost and ServerPort parameters. When launched from the command line as above with no command line arguments, these two parameters default to localhost and 9000.

2. Open a second terminal window and launch uXMS, passing it the --all command line switch. Just hit ENTER when prompted for the IP address and Port number, accepting the defaults of localhost and 9000. It should look something like:

After the above initial standard MOOSApp output, you should see a sequence of uxms reports similar to:

```
uXMS_443
                                                         0/0(31)
VarName
                   (S) (T) (C) VarValue (SCOPING: EVENTS)
                                   "uXMS_443,"
DB_CLIENTS
DB_EVENT
                                   "connected=uXMS_443"
DB_QOS
                                   "uXMS_443=0.448942:0.573874:0.364065:0.490189,"
DB_TIME
                                   1424028179.877422
DB_UPTIME
                                   16.741557
UXMS_443_ITER_GAP
                                   1.019045
UXMS_443_ITER_LEN
                                   0.00024
  -- displaying all variables --
```

Notice the number in parentheses on the second line is incrementing. This indicates that the report has been refreshed to your terminal. If you launched as above, the scope should come up in a mode that refreshes the report any time a scoped variable changes values. In this case, the MOOSDB is updating DB_TIME and DB_UPTIME about once per second. By default, uXMS only scopes on the variables named on the command line. In the above case, the --all option was used to tell uXMS to scope on all variables known to the MOOSDB.

The three variables shown beginning with DB₋ are all published by the MOOSDB. The user may choose whether or not to show the variable (S)ource, (T)ime of post, or (C)ommunity from where the post was made. A key feature of uxms vs. ums is the ability to specify on the command-line exactly which subset of variables to scope, possibly with color-coding. This is helpful when there are hundreds of variables in the DB.

3.2 More Suggested Tinkering with uXMS

Try a few other things:

- 2. Hit the space-bar to pause the stream of reports. This is useful if numbers are changing rapidly and you just need to take a close look at something. Return to the previous mode by hitting 'e'.
- 3. Hit the 's' key to expand the (S)ource column. This column tells you which app made the last posting. Try the same for the (T)ime and (C)ommunity columns.
- 4. The whole purpose of a scope is to give you the key information you're looking for, without needing to sift through a lot of unwanted information, with as little effort as possible. In this step we'll pretend to be interested in focusing our attention on the DB_UPTIME variable. Try launching uXMS with an additional command line argument:

```
$ uXMS --all --colormap=DB_UPTIME,blue
```

This may seem unnecessary when there are only three variables, but in real applications there

may be hundreds of variables. In fact, the variable you're looking for may have scrolled of the window!

5. A similar way to focus on a single variable is to only scope on the one variable we're looking for:

□ 只顯示—個var \$ uXMS DB_UPTIME

6. uXMS only shows you the current snapshot of the variables in the MOOSDB. What if you would like to see how a variable is changing? In our case, we know how the DB_UPTIME variable is changing, but for the sake of showing this feature, try:

3.3 Scoping with uMS

The uMS scope is a graphical MOOS scope, often preferred by those inclined to like GUIs vs. command line tools. It has some other advantages over uXMS as well.

Your goals in this part are:

1. If you don't still have a MOOSDB running, open a terminal window and launch the MOOSDB as done previously:

\$ MOOSDB

2. Open a second terminal window and launch uMS, passing it the same mission file as an argument:

\$ uMS

You should see a window open and, after clicking on the Connect button, you should see something similar to:

uXMS vs uMS 阿不就有圖形介面好棒棒

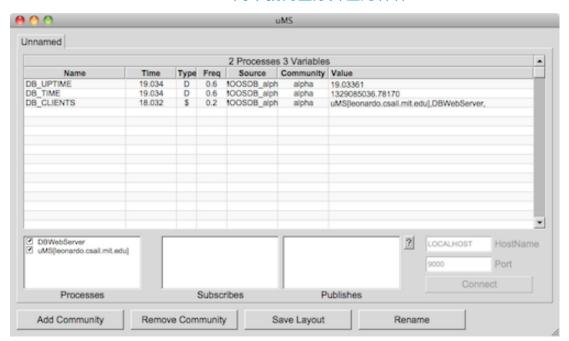

Figure 3: The uMS MOOS Scope

3.4 Pros/Cons of uXMS vs uMS

The choice of uXMS vs uMS is often just a matter of taste. A couple of differences are noteworthy however.

- uMS allows for connections to multiple MOOSDBs, on perhaps multiple vehicles, simultaneously. The user may select the vehicle with the tab at the top of the screen.
- uXMS allows the user to scope on as few as one single variable, or to name the variable scope 國可以鎖很少var list explicitly. uMS scopes on all variables all the time, with a few mechanisms for reducing the 國一次都跳全部 scope list based on process name.
 - uXMS may be a better choice if one is scoping on a remote MOOSDB, perhaps on a robot with a poor connection. It is a low-bandwidth client compared to uMS. If running on a remote terminal, its bandwidth back to the user is zero in the paused mode.
 - uxms has provisions for at least limited scoping on a variable history.
 - uxms will display a variable's "auxiliary source" information. This is a secondary field associated with each posting describing the source of the posting. This is key when using the IvPHelm. Variables posted by helm behaviors will have a source of pHelmIvP and an auxiliary source showing the behavior responsible for the posting.

4 Poking the MOOSDB

Poking refers to the idea of publishing a variable-value pair to the MOOSDB. Many apps publish to the MOOSDB during the course of normal operation. Poking implies a publication that perhaps was not planned, or outside the normal mode of business. It is often very useful for debugging. Here we describe the uPokeDB tool.

Where to get more information:

• uPokeDB: http://oceanai.mit.edu/ivpman/apps/uPokeDB

4.1 Poking the MOOSDB with uPokeDB 來为! POKE—下換血,戳—下換var或新增var

uPokeDB is a command-line tool for poking the MOOSDB with one or more variable-value pairs. Poking the MOOSDB requires knowing where the MOOSDB is running in terms of its IP address, ServerHost, and port number, ServerPort. These may be specified on the command line to uPokeDB, but for our purposes here we assume the existence of a mission file, alpha.moos with this information:

```
// A simple mission file, alpha.moos
ServerHost = localhost
ServerPort = 9000
Community = alpha
```

Your goals in this part are:

1. Open two terminal windows and launch the MOOSDB and uXMS as done previously:

```
$ MOOSDB alpha.moos
$ uXMS alpha.moos --all
```

Now open a third terminal window for poking the MOOSDB as follows:

```
$ uPokeDB DEPLOY=true SPEED=2 alpha.moos
```

Note the two new variables, DEPLOY and SPEED, appearing in the uXMS window. It should look something like:

```
uXMS_655
                                                   0/0(204)
           (S) (T) (C) VarValue (SCOPING: EVENTS)
VarName
                ---
                         "uXMS_655,"
DB_CLIENTS
DB_TIME
                         1386249435.276804
DB_UPTIME
                         46.213629
DEPLOY
                         "true"
                                                    只有string double兩種資料型態 R
SPEED
                         2
```

2. Note the variable values in uXMS. DEPLOY has the value "true" with double quotes, indicating that it is a string. The variable SPEED is of type double, indicated by the lack of quotes. The

傳數字字串加冒號

types were inferred by uPokeDB by heuristically checking whether the arguments are numerical or not. But sometimes you do want to publish a string with a numerical value. Try posting the variable HEIGHT with the string value of "192", noting the colon-equals instead of equals:

```
$ uPokeDB HEIGHT:=192 alpha.moos
```

Note the new variable, HEIGHT, appearing in the uXMS window. It should look something like the below output, where in this case, the (S) ource column is expanded to show the source of the postings.

uXMS_655				0/0(347)
VarName	(S)ource	(T)	(C)	VarValue (SCOPING:EVENTS)
DB_CLIENTS DB_TIME DB_UPTIME DEPLOY HEIGHT	MOOSDB_alpha MOOSDB_alpha MOOSDB_alpha uPokeDB uPokeDB			"uXMS_655," 1386250092.847527 703.784353 "true" "192"
SPEED	uPokeDB			2

4.2 Further things to try Using uPokeDB

Here's some other things to consider and try:

1. Trying poking the DEPLOY variable to the MOOSDB a second time, this time with:

```
$ uPokeDB DEPLOY=100 alpha.moos
```

Does the value of DEPLOY change? If not, why not?

2. Create a simple script of pokes on the command line as follows:

```
$ uPokeDB APPLES=1 alpha.moos; sleep 5; uPokeDB APPLES=2 alpha.moos;
```

If you're new to the command line environment, the semicolon above separates successful command line invocations. The sleep command is a common shell utilitity that will simply pause a given number of seconds before completing.

3. Another way to execute the same simple script as above is to store the above three commands in a file named, for example, myscript:

```
uPokeDB APPLES=1 alpha.moos
sleep 5
uPokeDB APPLES=2 alpha.moos
```

With the above file you can make the two successive pokes to the MOOSDB, with five seconds in between, with:

```
$ source myscript
```

There are many other ways of poking the MOOSDB. All MOOS apps that publish anything are examples. Of course many MOOS applications publish a fixed set of variables that are not easily changeable without re-coding. But certain apps like uTimerScript and pMarineViewer have built-in configuration file parameters for poking the MOOSDB in user configurable ways.

阿就要開好多個分頁一行一行貼很慢

5 Launching a Mission with pAntler 就懶惰做成—個launch file 跟roslaunch—樣

In theory a set of N MOOS applications may be launched from N terminal windows, but this is cumbersome in practice. The pantler tool allows this to be done from a single mission file. In this file, a block of lines declares all the apps to be launched with one invocation of pantler.

Where to get more information:

• pAntler: http://oceanai.mit.edu/ivpman/apps/pAntler

5.1 Basic pAntler Usage

通常都放在.moos的一開頭拉~ 然後可以設定每個要run的app要隔幾秒這樣

The Antler block is typically the first configuration block in a .moos file, declared with ProcessConfig = ANTLER as below. The MSBetweenLaunches parameter specifies the number of milliseconds between launching processes. Each line thereafter specifies an app to be launched and whether a dedicated console window should be opened for the application.

可以打開自己亂取的command

Further options exist beyond the vanilla launch configuration described above, including (a) the ability to launch a given app under an aliased name, (b) specifying command-line arguments to an app at launch time and more. See the documentation.

5.2 An Example: Launching the MOOSDB along with uXMS

In the example below we use pAntler to launch the MOOSDB and the uXMS scope from a single mission file. The user preferences for uXMS are provided in its configuration block. Type uXMS --example on the command line for further options.

Your goals in this part are:

1. Create a copy of the example mission file shown in Listing 1 below and save it locally as db_and_uxms.moos. (hint: the easiest way to do this is to just invoke the wget expression on the top line of this file. This will pull the file down from the server into your current directory.) The mission may be launched from the command-line with:

```
$ pAntler db_and_uxms.moos
```

This should open a new console window for uXMS displaying the variables posted by the DB, with the (S)ource and (T)ime columns expanded, but not the (C)ommunity column.

uXMS還是要先開起來

2. Modify the uXMS configuration block in the .moos file to configure uXMS to keep a history of the DB_UPTIME variable. To see configuration options for uXMS, type:

```
$ uXMS --example
```

Once you have launched uXMS with the new configuration, type 'z' to toggle in and out of history mode.

3. Modify the db_and_uxms.moos file to launch a new terminal window for the MOOSDB in addition to the uXMS application.

Listing 5.1: A simple mission file.

wget神器,給網址就可以把那個檔案載下來

```
// (wget http://oceanai.mit.edu/2.680/examples/db_and_uxms.moos)
ServerHost = localhost
ServerPort = 9000
Community = alpha
ProcessConfig = ANTLER
 MSBetweenLaunches = 200
                                               乾飞为力,要去載XQuartz阿~
  Run = MOOSDB
                 @ NewConsole = false
                                              不然一輩子跑不出來QQ
                 @ NewConsole = true
  Run = uXMS
ProcessConfig = uXMS
 AppTick = 4
 CommsTick = 4
               = DB_CLIENTS, DB_UPTIME, DB_TIME
 VAR
 DISPLAY_SOURCE = true
 DISPLAY_TIME = true
 COLOR_MAP
               = DB_CLIENTS, red
```

6 Scripted Pokes to the MOOSDB

Here we cover how to have a script of pre-arranged pokes to the MOOSDB. This may be useful for a number of reasons besides debugging. The primary tool described here is the uTimerScript MOOS application. It is capable of (a) scripted pokes at a pre-defined times after launch, (b) pokes having a poke-time specified to fall randomly within an specified interval, (c) pokes having numerical values falling with a uniformly random interval, and several other features including conditioning the running of the script based on other MOOS variables.

Where to get more information:

• uTimerScript: http://oceanai.mit.edu/ivpman/apps/uTimerScript

6.1 Basic uTimerScript Usage

uTimerScript is configured with its own block in the MOOS configuration file. The general format is below. The primary entries are the events themselves, defined by a MOOS variable, value, and time or time-range when the event is to occur. There are many options for configuring the script. These options are described in the documentation, but a quick look at the options can be seen by typing uTimerScript --example on the command line.

```
ProcessConfig = uTimerScript
{
  event = var=<M00SVar>, val=<value>, time=<value>
  event = var=<M00SVar>, val=<value>, time=<value>
  ...
  event = var=<M00SVar>, val=<value>, time=<value>
  [OPTIONS]
}
```

6.2 A Simple Example with uTimerScript

The below mission file contains a uTimerScript script for repeatedly posting the variable COUNTER_A with values 1-10 in ascending order roughly once every half second. The last event in the script is posted at time chosen from a random five second interval.

Listing 6.1: A simple counter example with uTimerScript.

```
// (wget http://oceanai.mit.edu/2.680/examples/utscript.moos)
ServerHost = localhost
ServerPort = 9000
Community = alpha
ProcessConfig = ANTLER
 MSBetweenLaunches = 200
 Run = MOOSDB
                  @ NewConsole = false
 Run = uTimerScript @ NewConsole = false
ProcessConfig = uXMS
 VAR
               = COUNTER_A, DB_CLIENTS, DB_UPTIME
 COLOR_MAP
             = COUNTER_A, red
 HISTORY_VAR
               = COUNTER_A
ProcessConfig = uTimerScript
                            這一項是拿來POKE的
 paused = false
 event = var=COUNTER_A, val=1, time=0.5
 event = var=COUNTER_A, val=2, time=1.0
 event = var=COUNTER_A, val=3, time=1.5
 event = var=COUNTER_A, val=4, time=2.0
 event = var=COUNTER_A, val=5, time=2.5
 event = var=COUNTER_A, val=6, time=3.0
 event = var=COUNTER_A, val=7, time=3.5
 event = var=COUNTER_A, val=8, time=4.0
 event = var=COUNTER_A, val=9, time=4.5
 event = var=COUNTER_A, val=10, time=5:10
 reset_max = nolimit
 reset_time = all-posted
```

The mission may be launched from the command-line with:

```
$ pAntler utscript.moos
```

This should open a new console window for uXMS displaying the variables COUNTER_A variable repeatedly

incrementing from 1 to 10. Note that reaching 10 happens somewhere between 0.5 and 5.5 seconds after reaching 9.

6.3 Exercises

Your goals in this part are:

- 1. Create a copy of the example mission file in Listing 1 above and save it locally.
- 2. Launch the mission. It should open a uXMS window. Follow the progress of the counter script.

```
$ pAntler utscript.moos
```

- 3. Take a look at the uTimerScript documentation linked from the web page. In particular, Section 6.3 Script Flow Control. Configure the script such that is paused when uTimerScript is launched. Launch the same mission and confirm that the script is initially not running. Then use uPokeDB to un-pause the script, and confirm it is running. Hint: to un-pause the script with uPokeDB, you'll need to know which variable to poke, and this also can be found in the uTimerScript documentation or by typing uTimerScript -i on the command line.
- 4. This is a bit of a pantler exercise. Configure your mission to launch two versions of the script, the second version publishing to COUNTER_B. Note you will need two configuration blocks, each with a unique name. And you will need to launch uTimerScript twice within the Antler block, each with an alias. Hint: see the pxRelay at the end of Lab 3.
- 5. Confirm your new mission launches and executes the two separate scripts and both counters are incrementing.
- 6. Configure the second script with a condition parameter. See Section 10.3.2 of the uTimerScript documentation. Use a condition such as "condition = COUNTER_A > 5". Re-launch your mission. Confirm that the second script is paused periodically based on the state of the first script.
- 7. Add the pLogger application to your mission. You will need to add a pLogger entry to your ANTLER configuration block, and add the following pLogger configuration block at the end of your file.

```
ProcessConfig = pLogger
{
   AsyncLog = true
   WildCardLogging = true
   WildCardOmitPattern = *_STATUS
}
```

Re-run the mission. Confirm that you see the pLogger application listed in the DB_CLIENTS variable in the uXMS scope.

- 8. Verify that a log file has been created. Since we didn't specify a name for the log file, by default it should be in a subdirectory of where you launched the mission, looking something like MOOSLog_11_23_2016____11_31_13/. Enter the directory and confirm that you see an .alog file.
- 9. Take a look at the file by typing more filename.alog. Then take at look at the COUNTER variables using aloggrep (substituting of course the name of your .alog file:

7 A Simple Example with pXRelay

pxRelay is a simple MOOS app designed solely to illustrate basic functions of a MOOS app. It registers for a single variable, and upon receiving mail for that variable, it publishes another variable incremented by 1. It provides a framework for illustrating a few other introductory topics.

7.1 Basic pXRelay Usage

outgoing = publish的概念 an incoming variable, the variable it will register for incoming mail, and (b) an outgoing variable, a variable it will post an incremented integer each time it receives mail on the incoming variable. The basic form is:

```
ProcessConfig = pXRelay
{
  outgoing_var = <MOOSVar>
  incoming_var = <MOOSVar>
}
```

7.2 A Simple Example with pXRelay

The below mission file contains a configuration for two instances of the pxrelay application. All MOOS apps must have a unique name to connect to the MOOSDB, so we launch them with an alias with pAntler using the pxrelay_PEARS alias for example. The two apps each register for what the other produces, and each produces what the other registers for.

Listing 7.2: Example Code.

```
// (wget http://oceanai.mit.edu/2.680/examples/xrelay.moos)
    ServerHost = localhost
 1
 2
    ServerPort = 9000
    Community = alpha
 3
 4
 5
    ProcessConfig = ANTLER
 6
7
      MSBetweenLaunches = 200
8
9
      Run = MOOSDB
                        @ NewConsole = false
10
      Run = pXRelay
                        @ NewConsole = false ~pXRelay_PEARS
                        @ NewConsole = false ~pXRelay_APPLES
11
      Run = pXRelay
12
13
                                       簡單來說就是每個node要有自己的名字拉~
    ProcessConfig = pXRelay_APPLES
14
                                       然後都是pXRelay_????這樣
15
16
      AppTick
                   = 10
      CommsTick
                   = 10
17
      incoming_var = APPLES
18
19
      outgoing_var = PEARS
20
    }
21
22
    ProcessConfig = pXRelay_PEARS
```

```
23 {
24    AppTick = 10
25    CommsTick = 10
26    incoming_var = PEARS
27    outgoing_var = APPLES
28 }
```

Upon launch, the two pXRelay apps are in a stalemate, each waiting for the other to make the first posting. We can break this stalemate with uPokeDB:

```
poke—下就會打破subscribe 跟publish之間的平衡
$ uPokeDB xrelay.moos PEARS=1
就開工樓~
```

This should get things going. Now it would be good to see it all running by launching a scope:

```
$ uXMS xrelay.moos --all --show=time
```

Your goals in this part are:

- 1. Create a copy of the example mission file shown in Listing 2 above and save it locally as pxrelay.moos. (hint: use wget!)
- 2. Launch the mission. Open up uXMS in another Terminal window with the parameters of your choosing. I recommend

```
$ uXMS pxrelay.moos --colorany=APPLES,PEARS --all
```

- 3. Kick off the activity by poking one of the APPLES or PEARS variables with an initial value. Confirm that things are working as they should.
- 4. Add uTimerScript to your mission file, with a simple script to kick off the pXRelay handshaking at some point after launch (say 10 secs), as an alternative way to kicking off the active instead of uPokeDB. You'll need to add uTimerScript to your ANTLER configuration block, and add a simple script (a uTimerScript configuration block) to your .moos file.
- 5. Change your uTimerScript script to be the ascending counter script from Section 6, incrementing COUNTER_A 1 to 10. Configure it with paused=false, but add a condition to your script (condition = APPLES == \$(PEARS). Re-launch the revised mission. Since APPLES is equal to PEARS periodically, the condition will periodically be met.
- 6. Try changing the AppTick in one of the pXRelay configurations to 0.1. You should note that the script is now mostly in the state where its conditions are not met. Can you explain why?

8 Modify the pXRelay Code

Next we will take the first steps toward extending the MOOS-IvP code. This is done by creating your own "third-party" tree, with your own MOOS apps. A template for this is available on the moos-ivp.org website: Go to www.moos-ivp.org and click on the moos-ivp-extend link in the lefthand menu. Download the moos-ivp-extend tree, in the same directory where the moos-ivp tree resides:

\$ svn co https://oceanai.mit.edu/svn/moos-ivp-extend/trunk moos-ivp-extend

Verify that you can build this tree by:

\$ cd moos-ivp-extend 下載新的package摟~

It should add the executable, pXRelayTest, in moos-ivp-extend/bin/.

Add the above directory to your shell path.

The moos-ivp-extend tree contains an app very similar to pXRelay from the moos-ivp tree. This app is call pXRelayTest. We will attempt to modify some of the behavior of the pXRelay application while putting our modifications in the new moos-ivp-extend tree, in pXRelayTest.

- 1. Take a look at the pXRelayTest source code. Look inside Relayer.cpp. Check out the OnNewMail() and Iterate() loops.
- 2. Can you modify this code to make its increments by ten instead of one?
- 3. Can you modify this code such that it takes *two* incoming variables, and does its thing if *either* of the two variables is written to?
